

# Specification and Proof of Programs with Frama-C

Nikolai Kosmatov

`firstname.lastname@cea.fr`

CEA LIST

CentraleSupélec, January 16, 2018

# Motivation

## Main objective:

Rigorous, mathematical proof of semantic properties of a program

- ▶ functional properties
- ▶ safety:
  - ▶ all memory accesses are valid,
  - ▶ no arithmetic overflow,
  - ▶ no division by zero, ...
- ▶ termination
- ▶ ...

# Our goal

In this lesson, we will see

- ▶ how (Floyd-)Hoare logic is used for proof of programs
- ▶ how to specify a C program
- ▶ how to prove it with an automatic tool
- ▶ how to understand and fix proof failures

# Outline

## Introduction

- Frama-C tool
- ACSL specification language
- WP plugin

## Hoare logic in a nutshell

## Programs without loops

- Pre- and postconditions
- Specification with behaviors
- Contracts and function calls

## Programs with loops

- Loop invariants
- Loop termination
- More exercises

## My proof fails... What to do?

## Conclusion

# Outline

## My proof fails... What to do?

## Conclusion

# Frama-C: A brief history

- ▶ 90's: [CAVEAT](#), a Hoare logic-based tool for C programs
- ▶ 2000's: [CAVEAT](#) used by Airbus during certification of the A380
- ▶ 2002: [Why](#) tool and its C front-end [Caduceus](#)
- ▶ 2006: Joint project to write a successor to CAVEAT and Caduceus
- ▶ 2008: First public release of [Frama-C](#) (Hydrogen)
- ▶ 2009: Hoare-logic based Frama-C plugin [Jessie](#) developed at INRIA
- ▶ 2012: New Hoare-logic based plugin [WP](#) developed at CEA LIST
- ▶ [Frama-C](#) today:
  - ▶ Most recent release: [Frama-C Sulfur \(v.16\)](#)
  - ▶ [Multiple projects](#) around the platform
  - ▶ A growing [community of users](#)

# Frama-C at a glance

- ▶ **FRA**mework for **M**odular **A**nalysis of **C** programs
  - ▶ **Various plugins**: CFG, value analysis (abstract interpretation), impact analysis, dependency analysis, slicing, program proof, ...
- ▶ Developed at CEA LIST and INRIA Saclay (Proval/Toccata team)
- ▶ Released under **LGPL license**
- ▶ Kernel based on **CIL library** [Necula et al. – Berkeley]
- ▶ Includes **ACSL specification language**
- ▶ **Extensible platform**
  - ▶ Adding specialized plugins is easy
  - ▶ **Collaboration of analyses** over the same code
  - ▶ Inter-plugin communication through ACSL formulas
- ▶ <http://frama-c.com/>

# ACSL: ANSI/ISO C Specification Language

## Presentation

- ▶ Based on the notion of contract, like in Eiffel
- ▶ Allows the users to specify functional properties of their programs
- ▶ Allows communication between various plugins
- ▶ Independent from a particular analysis
- ▶ ACSL manual at <http://frama-c.com/acsl.html>

## Basic Components

- ▶ First-order logic
- ▶ Pure C expressions
- ▶ C types +  $\mathbb{Z}$  (integer) and  $\mathbb{R}$  (real)
- ▶ Built-ins predicates and logic functions, particularly over pointers:  
`\valid(p)` `\valid(p+0..2)`, `\separated(p+0..2,q+0..5)`,  
`\block_length(p)`

# WP plugin

- ▶ Hoare-logic based plugin, developed at INRIA Saclay
- ▶ Proof of functional properties of the program
- ▶ Modular verification (function per function)
- ▶ Input: a program and a specification in ACSL
- ▶ WP generates verification conditions (VCs)
- ▶ Use of Automatic Theorem Provers to discharge the VCs
  - ▶ Alt-Ergo, Simplify, Z3, Yices, CVC3, ...
- ▶ If all VCs are proved, the program respects the given specification
  - ▶ Does it mean that the program is correct?

# WP plugin

- ▶ Hoare-logic based plugin, developed at INRIA Saclay
- ▶ Proof of functional properties of the program
- ▶ Modular verification (function per function)
- ▶ Input: a program and a specification in ACSL
- ▶ WP generates verification conditions (VCs)
- ▶ Use of Automatic Theorem Provers to discharge the VCs
  - ▶ Alt-Ergo, Simplify, Z3, Yices, CVC3, ...
- ▶ If all VCs are proved, the program respects the given specification
  - ▶ Does it mean that the program is correct?
  - ▶ If the specification is wrong, the program can be wrong
- ▶ Limitations
  - ▶ Casts between pointers and integers
  - ▶ Limited support for union type
  - ▶ Aliasing requires some care...

# In this lesson

## In this lesson we use

- ▶ Frama-C
- ▶ WP plug-in
- ▶ Alt-Ergo

## To run Frama-C/WP on a C program `file.c`

- ▶ `frama-c -wp file.c`

## To run Frama-C/WP also for assertions preventing runtime errors

- ▶ `frama-c -wp -wp-rte file.c`

# Outline

## Introduction

- Frama-C tool
- ACSL specification language
- WP plugin

## Hoare logic in a nutshell

### Programs without loops

- Pre- and postconditions
- Specification with behaviors
- Contracts and function calls

### Programs with loops

- Loop invariants
- Loop termination
- More exercises

### My proof fails... What to do?

## Conclusion

# Contracts

- ▶ **Goal:** specification of imperative functions
- ▶ **Approach:** give assertions (i.e. properties) about the functions
  - ▶ **Precondition** is supposed to be true on entry (ensured by callers of the function)
  - ▶ **Postcondition** must be true on exit (ensured by the function if it terminates)
- ▶ Nothing is guaranteed when the precondition is not satisfied
- ▶ **Termination** may or may not be guaranteed (total or partial correctness)

## Primary role of contracts

- ▶ Main input of the verification process
- ▶ Must reflect the informal specification
- ▶ Should not be modified just to suit the verification tasks

# What is Hoare Logic?

- ▶ A **formal system** allowing to reason about programs (by Floyd 1967, Hoare 1969, . . . )
- ▶ **Main idea**: provided some property is satisfied before some command, show another property after the execution of the command
- ▶ A **Hoare triple**:  $\{P\} C \{Q\}$  where  $P, Q$  are assertions and  $C$  is a command (a piece of program)
- ▶ **Assertions** are first-order formulae over program variables
- ▶ The Hoare triple  $\{P\} C \{Q\}$  is **valid** if
  - ▶ whenever  $P$  is true before  $C$  and  $C$  terminates,  $Q$  is true after  $C$
- ▶ **Termination** is not guaranteed (partial correctness)
  - ▶ If necessary, it may be proved separately (total correctness, cf below)
- ▶ Ex.:  $\{30 = z\} x := 10; y := 20 \{x + y = z\}$  is valid
- ▶ Ex.:  $\{30 = z\} x := 10; y := 20; z := t \{x + y = z\}$  is not valid

# Hoare logic rules

- ▶ A set of **inference rules** of the form

$$\frac{P_1 \quad P_2 \quad \dots \quad P_k}{Q}$$

- ▶ **Means:** if **premises**  $P_1, \dots, P_k$  are all true, then **conclusion**  $Q$  is true
- ▶ A rule without premises is an **axiom**
- ▶ A **proof** in Hoare logic deduces valid Hoare triples using inference rules, for example:

$$\frac{R \quad \frac{\{1 + 2 \leq z\} x := 1 \{x + 2 \leq z\}}{\{3 = z\} x := 1 \{x + 2 \leq z\}} \quad \frac{\{x + 2 \leq z\} y := 2 \{x + y \leq z\}}{\{3 = z\} x := 1; y := 2 \{x + y \leq z\}}}{\{3 = z\} x := 1; y := 2 \{x + y \leq z\}}$$

where  $R$  is  $3 = z \Rightarrow 3 \leq z$

# The rules

$$\text{skip} \frac{}{\{Q\} \text{ skip } \{Q\}}$$

$$\text{ass} \frac{}{\{Q[x \leftarrow e]\} x := e \{Q\}}$$

$$\text{seq} \frac{\{P\} C_1 \{Q\} \quad \{Q\} C_2 \{R\}}{\{P\} C_1; C_2 \{R\}}$$

$$\text{if} \frac{\{P \wedge e\} C_1 \{Q\} \quad \{P \wedge \neg e\} C_2 \{Q\}}{\{P\} \text{ if } e \text{ then } C_1 \text{ else } C_2 \{Q\}}$$

$$\text{while} \frac{\{I \wedge e\} C \{I\}}{\{I\} \text{ while } e \text{ do } C \{I \wedge \neg e\}}$$

$$\text{cons} \frac{P \Rightarrow P' \quad \{P'\} C \{Q'\} \quad Q' \Rightarrow Q}{\{P\} C \{Q\}}$$

$Q[x \leftarrow e]$  is the assertion  $Q$  where all free occurrences of  $x$  are replaced by  $e$

## More proof examples

Identify the rules being applied, and complete:

- $\{true\}$  if  $x > 10$  then  $y := 10$  else  $y := x \{y \leq 10\}$

$$\frac{\frac{x > 10 \Rightarrow 10 \leq 10 \quad \overline{\{10 \leq 10\} y := 10 \{y \leq 10\}}}{\{x > 10\} y := 10 \{y \leq 10\}} \quad \overline{\{x \leq 10\} y := x \{y \leq 10\}}}{\{true\} \text{ if } x > 10 \text{ then } y := 10 \text{ else } y := x \{y \leq 10\}}$$

- $\{x \geq 0\} n := 0; \text{ while } n < x \text{ do } n := n + 1 \{n = x\}$

$$\frac{\frac{\vdots}{\{0 \leq x\} n := 0 \{0 \leq n \leq x\}} \quad \frac{\frac{\vdots}{\{0 \leq n \leq x \wedge n < x\} n := n + 1 \{0 \leq n \leq x\}}}{\{0 \leq n \leq x\} \text{ while } n < x \text{ do } n := n + 1 \{0 \leq n \leq x \wedge n \geq x\}}}{\{0 \leq x\} n := 0; \text{ while } n < x \text{ do } n := n + 1 \{n = x\}}$$

## My proof fails... What to do?

## Conclusion

# Safety warnings: arithmetic overflows

Absence of arithmetic overflows can be important to check

- ▶ A sad example: crash of Ariane 5 in 1996
- ▶ WP can automatically generate VCs to check absence of overflows (option `-wp-rte`)
- ▶ They ensure that arithmetic operations do not overflow
- ▶ If not proved, an overflow may occur. [Is it intended?](#)

# Safety warnings: invalid memory accesses

An invalid pointer or array access may result in a **segmentation fault or memory corruption**.

- ▶ WP can automatically generate VCs to check memory access validity (option `-wp-rte`)
- ▶ They ensure that each pointer (array) access has a **valid offset (index)**
- ▶ If the function assumes that an input pointer is valid, it must be **stated in its precondition**, e.g.
  - ▶ `\valid(p)` for one pointer `p`
  - ▶ `\valid(p+0..2)` for a range of offsets `p`, `p+1`, `p+2`

# Frame rule

The clause `assigns v1, v2, ... , vN;`

- ▶ Part of the postcondition
- ▶ Specifies which (non local) variables can be modified by the function
- ▶ No need to specify local variable modifications in the postcondition
  - ▶ a function is allowed to change local variables
  - ▶ a postcondition cannot talk about them anyway, they do not exist after the function call
- ▶ Avoids to state that for any unchanged global variable  $v$ , we have `ensures \old(v) == v`
- ▶ Avoids to forget one of them: explicit permission is required
- ▶ If nothing can be modified, specify `assigns \nothing`

# Behaviors

## Specification by cases

- ▶ Global precondition (**requires**) applies to all cases
- ▶ Global postcondition (**ensures**, **assigns**) applies to all cases
- ▶ Behaviors define contracts (refine global contract) in particular cases
- ▶ For each case (each **behavior**)
  - ▶ the subdomain is defined by **assumes** clause
  - ▶ the behavior's precondition is defined by **requires** clauses
    - ▶ it is supposed to be true whenever **assumes** condition is true
  - ▶ the behavior's postcondition is defined by **ensures**, **assigns** clauses
    - ▶ it must be ensured whenever **assumes** condition is true
- ▶ **complete behaviors** states that given behaviors cover all cases
- ▶ **disjoint behaviors** states that given behaviors do not overlap

# Contracts and function calls

Function calls are handled as follows:

- ▶ Suppose function  $g$  contains a call to a function  $f$
- ▶ Suppose we try to prove the caller  $g$
- ▶ Before the call to  $f$  in  $g$ , the precondition of  $f$  must be ensured by  $g$ 
  - ▶ VCs is generated to prove that the precondition of  $f$  is respected
- ▶ After the call to  $f$  in  $g$ , the postcondition of  $f$  is supposed to be true
  - ▶ the postcondition of  $f$  is assumed in the proof below
  - ▶ modular verification: the code of  $f$  is not checked at this point
  - ▶ only a contract and a declaration of the callee  $f$  are required

Pre/post of the caller and of the callee have dual roles in the caller's proof

- ▶ Pre of the caller is supposed, Post of the caller must be ensured
- ▶ Pre of the callee must be ensured, Post of the callee is supposed

# Outline

## Introduction

- Pre- and postconditions
- Specification with behaviors
- Contracts and function calls

## Programs with loops

- Loop invariants
- Loop termination
- More exercises

## My proof fails... What to do?

## Conclusion

# Loops and automatic proof

- ▶ What is the issue with loops? Unknown, **variable number of iterations**
- ▶ The only possible way to handle loops: **proof by induction**
- ▶ Induction needs a suitable **inductive property**, that is proved to be
  - ▶ satisfied just before the loop, and
  - ▶ satisfied after  $k + 1$  iterations whenever it is satisfied after  $k \geq 0$  iterations
- ▶ Such inductive property is called **loop invariant**
- ▶ The verification conditions for a loop invariant include two parts
  - ▶ **loop invariant initially holds**
  - ▶ **loop invariant is preserved** by any iteration

## Loop invariants - some hints

How to find a suitable loop invariant? Consider two aspects:

- ▶ identify **variables modified in the loop**
  - ▶ variable number of iterations prevents from deducing their values (relationships with other variables)
  - ▶ define their possible value intervals (relationships) after  $k$  iterations
  - ▶ use **loop assigns** clause to list variables that (might) have been assigned so far after  $k$  iterations
- ▶ identify realized actions, or **properties already ensured by the loop**
  - ▶ what **part of the job** already realized after  $k$  iterations?
  - ▶ what **part of the expected loop results** already ensured after  $k$  iterations?
  - ▶ why the next iteration can proceed as it does? ...

A **stronger property** on each iteration may be required to prove the final result of the loop

Some experience may be necessary to find appropriate loop invariants

# Loop invariants - more hints

Remember: a loop invariant must be true

- ▶ before (the first iteration of) the loop, even if no iteration is possible
- ▶ after any complete iteration even if no more iterations are possible
- ▶ in other words, any time before the loop condition check

In particular, a **for** loop

```
for (i=0; i<n; i++) { /* body */ }
```

should be seen as

```
i=0;           // action before the first iteration
while ( i<n ) // an iteration starts by the condition check
{
    /* body */
    i++;       // last action in an iteration
}
```

# Loop termination

- ▶ Program termination is undecidable
- ▶ A tool cannot deduce neither the exact number of iterations, nor even an upper bound
- ▶ If an upper bound is given, a tool can check it by induction
- ▶ An upper bound on the number of remaining loop iterations is the key idea behind the loop variant

## Terminology

- ▶ Partial correctness: if the function terminates, it respects its specification
- ▶ Total correctness: the function terminates, and it respects its specification

## Loop variants - some hints

- ▶ Unlike an invariant, a loop variant is an **integer expression**, not a predicate
- ▶ Loop variant is **not unique**: if  $V$  works,  $V + 1$  works as well
- ▶ No need to find a precise bound, any working loop variant is OK
- ▶ To find a variant, **look at the loop condition**
  - ▶ For the loop **while**( $\text{exp1} > \text{exp2}$ ), try **loop variant**  $\text{exp1} - \text{exp2}$ ;
- ▶ In more complex cases: ask yourself why the loop terminates, and try to give an integer upper bound on the number of remaining loop iterations

# \forall and \exists - hints and examples

- ▶ Do not confuse `&&` and `==>` inside `\forall` and `\exists`
- ▶ Some common patterns:
  - ▶ `\forall integer j; 0 <= j && j < n ==> t[j] == 0;`
  - ▶ `\exists integer j; 0 <= j && j < n && t[j] != 0;`
  - ▶ Each one here is negation of the other
- ▶ A shorter form:
  - ▶ `\forall integer j; 0 <= j < n ==> t[j] == 0;`
  - ▶ `\exists integer j; 0 <= j < n && t[j] != 0;`
- ▶ With several variables:
  - ▶ `\forall integer i,j; 0 <= i <= j < length ==> a[i]<=a[j];`
  - ▶ `\exists integer i,j; 0 <= i <= j < length && a[i]>a[j]`

# Referring to another state

- ▶ Specification may require **values at different program points**
- ▶ Use `\at(e,L)` to refer to the value of expression `e` at label `L`
- ▶ Some predefined labels:
  - ▶ `\at(e,Here)` refers to the current state
  - ▶ `\at(e,Old)` refers to the pre-state
  - ▶ `\at(e,Post)` refers to the post-state
- ▶ `\old(e)` is equivalent to `\at(e,Old)`

# Outline

## My proof fails... What to do?

## Conclusion

# Proof failures

A proof of a VC for some annotation can fail for **various reasons**:

- ▶ incorrect implementation ( $\rightarrow$  check your code)
- ▶ incorrect annotation ( $\rightarrow$  check your spec)
- ▶ missing or erroneous (previous) annotation ( $\rightarrow$  check your spec)
- ▶ insufficient timeout ( $\rightarrow$  try longer timeout)
- ▶ complex property that automatic provers cannot handle.

# Analysis of proof failures

When a proof failure is due to the specification, the erroneous annotation may be **not obvious to find**. For example:

- ▶ proof of a “**loop invariant preserved**” may fail in case of
  - ▶ incorrect loop invariant
  - ▶ incorrect loop invariant in a previous, or inner, or outer loop
  - ▶ missing **assumes** or **loop assumes** clause
  - ▶ too weak precondition
  - ▶ ...
- ▶ proof of a **postcondition** may fail in case of
  - ▶ incorrect loop invariant (too weak, too strong, or inappropriate)
  - ▶ missing **assumes** or **loop assumes** clause
  - ▶ inappropriate postcondition in a called function
  - ▶ too weak precondition
  - ▶ ...

## Analysis of proof failures (Continued)

- ▶ Additional statements (`assert`, `lemma`, ...) may help the prover
  - ▶ They can be provable by the same (or another) prover or checked elsewhere
- ▶ Separating independent properties (e.g. in separate, non disjoint behaviors) may help
  - ▶ The prover may get lost with a bigger set of hypotheses (some of which are irrelevant)

### When nothing else helps to finish the proof:

- ▶ an `interactive proof assistant` can be used
- ▶ Coq, Isabelle, PVS, are not that scary: we may need only a small portion of the underlying theory

# Outline

## My proof fails... What to do?

## Conclusion

# Conclusion

- ▶ We learned how to specify and prove a C program with Frama-C
- ▶ Hoare-logic based tools provide a powerful way to **formally verify programs**
- ▶ The program is proved **with respect to the given specification**, so
  - ▶ Absence of proof failures is not sufficient
  - ▶ **The specification must be correct**
- ▶ The proof is **automatic**, but analysis of proof failures is **manual**
- ▶ **Proof failures** help to complete the specification or find bugs
- ▶ **Interactive proof tools** may be necessary to finish the proof for complex properties that cannot be proved automatically
